THE STRUCTURE OF THE LINEARLY ORDERED COMPACTIFICATIONS OF GO-SPACES

NOBUYUKI KEMOTO

Abstract. A linearly ordered extension of a GO-space \( X \) is a LOTS \( L \) such that the LOTS \( L \) contains the GO-space \( X \) as a subspace and the order \( <_L \) on \( L \) extends the order \( <_X \) on \( X \), moreover if \( X \) is dense in \( L \), then \( L \) is called a linearly ordered d-extension. A linearly ordered compactification of a GO-space \( X \) is a compact linearly ordered d-extension of \( X \). We will visualize all linearly ordered compactifications of a given GO-space in a certain way. For a given linearly ordered set \( \langle X, <_X \rangle \), \( L_X \) denotes the class of all linearly ordered compactifications of GO-spaces whose underlying linearly ordered set is \( \langle X, <_X \rangle \). We will also see the partial order structure \( \langle L_X, \leq \rangle \), where \( L_0 \leq L_1 \) if there is a continuous map \( f : L_1 \to L_0 \) such that \( f(x) = x \) for every \( x \in X \), is order isomorphic to the product \( \langle P(A), \subseteq \rangle \times \langle P(B), \subseteq \rangle \times \langle P(C), \subseteq \rangle \) for some sets \( A, B \) and \( C \), where \( \langle P(A), \subseteq \rangle \) denotes the partial ordered set of the set of all subset of \( A \) with the usual inclusion. The sets \( A, B \) and \( C \) will be described exactly. Moreover, we will see that the partial order structure on the class of all linearly ordered compactifications of a fixed GO-space only depends on its underlying linearly ordered set, does not depend on its topology.

1. Introduction

We assume that all topological spaces have cardinality at least 2. We will prove the results in the abstract. At first, we give precise definitions for later arguments.

A linearly ordered set \( \langle L, <_L \rangle \) (see [1]) has a natural \( T_2 \)-topology \( \lambda(<_L) \) so called the interval topology which is the topology generated by \( \{(\leftarrow, u)_L : u \in L\} \cup \{ (u, \rightarrow)_L : u \in L \} \) as a subbase, where \( \langle \leftarrow, u \rangle_L = \{ w \in L : w <_L u \} \) and \( \langle u, \rightarrow \rangle_L = \{ w \in L : u <_L w \} \). Also we denote \( \{ w \in L : u <_L w \leq_L v \} \) by \( [u, v]_L \), and \( \{ u, v \}_L, \langle u, v \rangle_L \), etc are similarly defined, where \( w \leq_L v \) means \( w <_L v \) or \( w = v \).

Key words and phrases. GO-space, LOTS, linearly ordered extensions, compact, connected.
If the contexts are clear, we write \(<\) and \([u, v]\) instead of \(<_L\) and \((u, v)_L\) respectively. Note that this subbase induces a base by convex subsets (e.g., the collection of all intersections of at most two members of this subbase), where a subset \(B\) of \(L\) is convex if for every \(u, v \in B\) with \(u <_L v\), \([u, v]_L \subseteq B\). The triple \(\langle L, <_L, \lambda(<_L)\rangle\) is called a LOTS (= Linearly Ordered Topological Space) and simply denoted by LOTS \(L\). Observe that if \(u \in U \in \lambda(<_L)\) and \((\leftarrow, u)_L \neq \emptyset\), then there is \(v \in L\) such that \(v <_L u\) and \((v, u)_L \subseteq U\). Also observe its analogous result. Unless otherwise stated, the real line \(\mathbb{R}\) is considered as a linearly ordered set (hence LOTS) with the usual order, similarly so are the set \(\mathbb{Q}\) of rationals, the set \(\mathbb{P}\) of irrationals and an ordinal \(\alpha\).

A triple \(\langle L, <_L, \tau\rangle\), where \(<_L\) is linear order on \(L\) and \(\tau\) is a \(T_2\) topology on \(L\), is called a GO-space (= Generalized ordered Space) if \(\tau\) has a base consisting of convex sets, also simply denoted by GO-space \(L\), see [4]. The pair \(\langle L, <_L\rangle\) (the triple \(\langle L, <_L, \lambda(<_L)\rangle\)) is said to be the underlying linearly ordered set (the underlying LOTS, respectively) of the GO-space \(L\) and such a topology \(\tau\) is called a GO-space topology on \(L\). It is easy to verify that \(\tau\) as described above is stronger than the topology \(\lambda(<_L)\) of the underlying linearly ordered set, that is, \(\tau \supset \lambda(<_L)\). Obviously every LOTS is a GO-space but not conversely, for example, the Sorgenfrey line \(\mathbb{S}\) is such an example.

Let \(L = \langle L, <_L, \lambda(<_L)\rangle\) be a LOTS and \(X = \langle X, <_X, \tau\rangle\) a GO-space with \(X \subseteq L\). If \(<_L\) extends \(<_X\) and the space \(\langle X, \tau\rangle\) is a subspace of \(\langle L, \lambda(<_L)\rangle\), that is \(\tau = \lambda(<_L) \upharpoonright X = \{U \cap X : U \in \lambda(<_L)\}\), then the LOTS \(L\) is called a linearly ordered extension of \(X\). Moreover if \(X\) is dense in \(L\), then the LOTS \(L\) is called a linearly ordered d-extension of \(X\), see [5]. A compact linearly ordered d-extension is called a linearly ordered compactification, see [2, 3, 6].

A pair \(\langle A, B\rangle\) of subsets of a linearly ordered set \(\langle L, <_L\rangle\) is called a cut if \(A \cup B = L\) and if \(u \in A\) and \(v \in B\) then \(u <_L v\). A cut is called a jump if \(A\) has a maximal element (denoted by \(\text{max} A\)) and \(B\) has a minimal element (denoted by \(\text{min} B\)). A cut \(\langle A, B\rangle\) is called a gap if \(A\) has no maximal element (we write, \(A\) has no max) and \(B\) has no min. In particular if \(A = \emptyset\) or \(B = \emptyset\), then \(\langle A, B\rangle\) is called an end gap, other gaps are called middle gaps. Usually if \(\langle \emptyset, X\rangle\) is a gap, then it is written as \(-\infty\). Similarly if \(\langle X, \emptyset\rangle\) is a gap, then it is written as \(\infty\). It is easy to verify:

- A compact GO-spaces is a LOTS.
- A LOTS \(L\) is compact iff the linearly ordered set \(L\) has no gaps.

Now let \(X = \langle X, <_X, \tau\rangle\) be a GO-space and \(\lambda = \lambda(<_X)\). Note that for every \(x \in X\), \((\leftarrow, x)_X \notin \lambda\) iff \((x, \rightarrow)_X\) is non-empty and has no min,
also analogously $[x, \rightarrow)_X \notin \lambda$ iff $(\leftarrow, x)_X$ is non-empty and has no max. Let

$$X_R = \{ x \in X : (\leftarrow, x)_X \notin \lambda \},$$

$$X_L = \{ x \in X : [x, \rightarrow)_X \notin \lambda \}.$$ 

Note that the definitions of $X_R$ and $X_L$ only depend on the underlying LOTS. Also let

$$X^+_\tau = \{ x \in X : (\leftarrow, x)_X \in \tau \setminus \lambda \},$$

$$X^-_\tau = \{ x \in X : [x, \rightarrow)_X \in \tau \setminus \lambda \}.$$ 

Obviously $X^+_\tau \subseteq X_R$ and $X^-_\tau \subseteq X_L$. Note that $X^+_\tau \cap X^-_\tau$ might be non-empty. If there is no confusion, we usually simply write $X^+$ and $X^-$ instead of $X^+_\tau$ and $X^-_\tau$. The following two lemmas are straightforward.

**Lemma 1.1.** In the situation above, the topology $\tau$ coincides with the topology generated by $\{ \langle \leftarrow, x \rangle_X : x \in X \} \cup \{ \langle x, \rightarrow \rangle_X : x \in X \} \cup \{ \langle \leftarrow, x \rangle_X : x \in X^+_\tau \} \cup \{ [x, \rightarrow)_X : x \in X^-_\tau \}$ as a subbase.

**Lemma 1.2.** Let $(X, <_X)$ be a linearly ordered set with $A \subseteq X_R$ and $B \subseteq X_L$. Moreover let $\tau(A, B)$ be the topology generated by $\{ \langle \leftarrow, x \rangle_X : x \in X \} \cup \{ \langle x, \rightarrow \rangle_X : x \in X \} \cup \{ \langle \leftarrow, x \rangle_X : x \in A \} \cup \{ [x, \rightarrow)_X : x \in B \}$ as a subbase. Then $\tau(A, B)$ is a GO-space topology and $A = X^+_{\tau(A, B)}$ and $B = X^-_{\tau(A, B)}$.

In the case $X = \mathbb{R}$, note $X_R = X_L = \mathbb{R}$. The Sorgenfrey line $\mathbb{S}$ is the GO-space $(\mathbb{R}, <_R, \tau(\emptyset, \mathbb{R}))$ and the Michael line $\mathbb{M}$ is the GO-space $(\mathbb{R}, <_R, \tau(\mathbb{P}, \mathbb{P}))$. Given a linearly ordered set $(X, <_X)$, let $GT_X$ be the set of all GO-space topologies on $(X, <_X)$, i.e.,

$$GT_X = \{ \tau : (X, <_X, \tau) \text{ is a GO-space.} \}.$$ 

We consider $GT_X$ as a partially ordered set $(GT_X, \subseteq)$ with the usual inclusion “$\subseteq$”, where $(\mathbb{P}, \leq)$ is a partially ordered set if $\leq$ is reflexive ($p \leq p$), transitive ($p \leq q, q \leq r \Rightarrow p \leq r$) and antisymmetric ($p \leq q, q \leq p \Rightarrow p = q$). For two partially ordered sets $(\mathbb{P}, \leq \mathbb{P})$ and $(\mathbb{Q}, \leq \mathbb{Q})$, one can define the partial order $\leq_{\mathbb{P} \times \mathbb{Q}}$ on the product $\mathbb{P} \times \mathbb{Q}$, that is, $\langle p, q \rangle \leq_{\mathbb{P} \times \mathbb{Q}} \langle p', q' \rangle$ iff $p \leq \mathbb{P} p'$ and $q \leq \mathbb{Q} q'$. This partial ordered set is denoted by $(\mathbb{P}, \leq \mathbb{P}) \times (\mathbb{Q}, \leq \mathbb{Q})$. Similarly we can define the product of 3 (and so on) partially ordered sets. Now, the two lemmas above show:

**Proposition 1.3.** Let $(X, <_X)$ be a linearly ordered set. Then the partially ordered set $(GT_X, \subseteq)$ is order isomorphic to the partial ordered set $(\mathbb{P}(X_R), \subseteq) \times (\mathbb{P}(X_L), \subseteq)$. 

Here two partially ordered sets \( (\mathbb{P}, \leq_p) \) and \( (\mathbb{Q}, \leq_q) \) are said to be \textit{order isomorphic} if there is a 1-1 onto map \( f : \mathbb{P} \to \mathbb{Q} \) such that \( p \leq_p p' \) iff \( f(p) \leq_p f(p') \). In the case \( X = \mathbb{R} \), the structure \( (\text{GT}_\mathbb{R}, \subseteq) \) is order isomorphic to \( (\mathcal{P}(\mathbb{R}), \subseteq) \times (\mathcal{P}(\mathbb{R}), \subseteq) \).

Given two linearly ordered set \( L_0 \) and \( L_1 \), one can define a order \( <_L \) on \( L = L_0 \times L_1 \) so called the \textit{lexicographic order} by:

\[ (u, v) <_L (u', v') \; \text{iff} \; u <_{L_0} u' \; \text{or} \; (u = u' \; \text{and} \; v <_{L_1} v'). \]

In the case \( Z \subseteq L_0 \times L_1 \), the restricted order \( <_{L_0 \times L_1} \mid Z \) of the lexicographic order \( <_{L_0 \times L_1} \) to \( Z \) is also called the \textit{lexicographic order} on \( Z \) and denoted by \( <_Z \).

Now for a given GO-space \( X = \langle X, <_X, \tau \rangle \), let

\[ X^* = (X^- \times \{-1\}) \cup (X \times \{0\}) \cup (X^+ \times \{1\}) \]

and consider the lexicographic order \( <_{X^*} \) on \( X^* \) induced by the lexicographic order on \( X \times \{-1, 0, 1\} \), here of course \(-1 < 0 < 1\). We usually identify \( X \) as \( X = X \times \{0\} \) in the obvious way (i.e., \( x = \langle x, 0 \rangle \)), thus we may consider \( X^* = (X^- \times \{-1\}) \cup X \cup (X^+ \times \{1\}) \). It is easy to verify that \( X^* \) is a linearly ordered d-extension of \( X \). Moreover, under the trivial identification, we may consider that \( X^* \) is the smallest linearly ordered d-extension of \( X \), that is, if \( L \) is a linearly ordered d-extension of \( X \) then \( X^* \subseteq L \), see [5, Theorem 2.1]. Note \( (\langle-, x \rangle_X = (\langle-, \langle x, 1 \rangle \rangle_{X^*} \cap X) \in \lambda(\langle-\rangle_{X^*}) \mid X \) whenever \( x \in X^+ \), and also its analogy. Using this fact and easy arguments, one can show:

**Lemma 1.4.** Let \( X = \langle X, <_X, \tau \rangle \) be a GO-space and consider the LOTS \( X^* = \langle X^*, <_{X^*}, \lambda(\langle-\rangle_{X^*}) \rangle \) defined above. Let \( L \) be a linearly ordered compactification of \( X \). Regarding \( X^* \subseteq L \), the following holds:

1. if \( x \in X^+ \), then \( (x, \langle x, 1 \rangle)_L = \emptyset \),
2. if \( x \in X^- \), then \( (x, \langle x, -1 \rangle)_L = \emptyset \),
3. if \( u \in L \), \( v \in X^- \times \{-1\} \) and \( u <_L v \), then \( (u, v)_L \cap X \neq \emptyset \),
4. if \( u \in L \), \( v \in X^+ \times \{1\} \) and \( v <_L u \), then \( (v, u)_L \cap X \neq \emptyset \),
5. if \( u, v \in X^* \setminus X \) and \( u <_{X^*} v \), then \( (u, v)_{X^*} \cap X \neq \emptyset \).

Let \( X = [0, 1] \cup (2, 3] \) and \( L = [0, 1] \cup [2, 3] \) be the subspaces of \( \mathbb{R} \). We may consider that \( X \) is a GO-space and \( L \) is a linearly ordered compactification of \( X \). In (5) in the lemma above, \( X^* \) cannot be replaced by \( L \), because the case \( “u = 1, v = 2” \) is witnessing.

2. Compact LOTS

In this section, we will present a machine from a compact LOTS making another compact LOTS.
First let $L$ be a LOTS. For a subset $W \subseteq L$, $L[W]$ denotes the LOTS $L \times \{0\} \cup W \times \{1\}$ with the lexicographic order $<_L[W]$. Also as above we identify $L \times \{0\}$ with $L$, so we may consider as $L[W] = L \cup W \times \{1\}$.

Obviously the interval topology $\lambda(<_L)$ is weaker than the subspace topology $\lambda(<_L[W]) \mid L$ and in general not equal. Remark that $L$ is not a subspace of $L[W]$ whenever $u \in \text{Cl}_L(u, \to)_L$ for some $u \in W$, because of $u \not\in \text{Cl}_L[W](u, \to)_L$, where $\text{Cl}_L$ denotes the closure with respect to $L$.

Later we use the following easy lemma:

**Lemma 2.2.** Let $f : L_1 \to L_0$ be an order preserving (i.e., $u <_{L_1} v \to f(u) \leq_{L_0} f(v)$) onto map between LOTS’s $L_1$ and $L_0$. Then the following holds:

1. If for each $y \in L_0$, $f^{-1}([y])$ has max and min, then $f$ is continuous.
2. Let $f$ be 2-1 (i.e., $\left| f^{-1}([y]) \right| \leq 2$ for each $y \in L_0$) and $W = \{ y \in L_0 : \left| f^{-1}([y]) \right| = 2 \}$. Then $\tilde{f} : L_1 \to L_0[W]$ defined by

$$\tilde{f}(u) = \begin{cases} (f(u), 1) & \text{if } u = \max f^{-1}([y]) \text{ for some } y \in W, \\ f(u) & \text{otherwise,} \end{cases}$$

is an order isomorphism, therefore the LOTS $L_1$ can be identified with the LOTS $L_0[W]$.

To see (1) in the lemma above, use the fact that $f^{-1}([\leftarrow, y]_{L_0})$ is equal to $\langle \leftarrow, \min f^{-1}([y]) \rangle_{L_1}$ whenever $\min f^{-1}([\leftarrow, y]_{L_0})$ exists. It is known:

**Lemma 2.2.** [1, Problem 3.12.3(a)] $L$ be a LOTS. Then the following are equivalent.

1. $L$ is compact.
2. Every subset $A$ of $L$, including $A = \emptyset$, has a least upper bound $\sup_L A$.
3. Every subset $A$ of $L$, including $A = \emptyset$, has a greatest lower bound $\inf_L A$.

Note $\sup_L \emptyset = \inf_L L = \min L$ and $\sup_L L = \inf_L \emptyset = \max L$ whenever $L$ is compact. Also note that $(\leftarrow, u)_L = \emptyset$ iff $u = \min L$ and analogously $(u, \to)_L = \emptyset$ iff $u = \max L$.

Now in the remaining of this section, fix a compact LOTS $L = \langle L, <_L, \lambda(<_L) \rangle$. Set

$$G(L) = \{ u \in L : u = \sup_L (\leftarrow, u)_L = \inf_L (u, \to)_L \};$$

$$G^M(L) = \{ u \in G(L) : (\leftarrow, u)_L \neq \emptyset, (u, \to)_L \neq \emptyset \}.$$

Note $G^M(L) = G(L) \setminus \{ \min L, \max L \}$. Note that if $W \subseteq G^M(L)$, then $\min L = \min L[W]$ and $\max L = \max L[W]$ hold.
Lemma 2.3. Let $L$ be a compact LOTS and $W \subseteq G^M(L)$. Then the following hold:

1. the LOTS $L|W$ is compact,
2. the subspace topology $\lambda(<_L) \upharpoonright (L \setminus W)$ on $L \setminus W$ coincides with the subspace topology $\lambda(<_{L|W}) \upharpoonright (L \setminus W)$,
3. if $L \setminus W$ is dense in $L$, then it is also dense in $L[W]$.

Proof. (1) and (2) are straightforward, for (3), assume that $L \setminus W$ is dense in $L$ and there is a non-empty open set $U$ in $L[W]$ disjoint from $L \setminus W$. Pick $u \in U$. First assume $u \in L$. Then we have $u \in W \subseteq G^M(L)$. Since $U$ is open in $L[W]$, we can pick $v \in L[W]$ with $v <_{L[W]} u$ and $(v, u)_{L[W]} \subseteq U$. In the case $v \in L$, by $u = \sup_L(\langle - , u \rangle_L, (v, u)_L)$ is non-empty open in $L$. Thus $\emptyset \neq (v, u)_L \cap (L \setminus W) \subseteq U \cap (L \setminus W) = \emptyset$, a contradiction. Next assume $u \in W \times \{1\}$, say $u = \langle u', 1 \rangle$ for some $u' \in W$. Similarly as above $(u', u)_L$ is non-empty open in $L$, then $\emptyset \neq (u', u)_L \cap (L \setminus W) = (v, u)_{L[W]} \cap (L \setminus W) \subseteq U \cap (L \setminus W) = \emptyset$, a contradiction. Next assume $u \in W \times \{1\}$, say $u = \langle u', 1 \rangle$ for some $w \in W$. Since $u <_{L[W]} v$, we have $u' <_L w$. Similarly as above $(u', w)_L$ is non-empty open in $L$, then $\emptyset \neq (u', w)_L \cap (L \setminus W) = (u, w)_{L[W]} \cap (L \setminus W) \subseteq U \cap (L \setminus W) = \emptyset$, a contradiction. This completes the proof. \qed

Now we have:

Corollary 2.4. Let $L$ be a compact LOTS and $W \subseteq G^M(L)$. If $X$ is dense in $L$ and $X \subseteq L \setminus W$, then $X$ is also a dense subspace of $L[W]$.

The following lemma may clarify the structure of $L[W]$.

Lemma 2.5. Let $L$ be a compact LOTS and $W \subseteq G^M(L)$.

1. If $u, v \in L$ and $u <_L v$ and $(u, v)_L = \emptyset$, then $(u, v)_{L[W]} = \emptyset$.
2. If $u \in G(L)$, then $u = \sup_L(\langle - , u \rangle_L) = \sup_{L[W]}(\langle - , u \rangle_L)$.
3. If $u \in G(L) \setminus W$, then $u = \inf_{L[W]}(\langle u , \rangle_L) = \inf_{L[W]}(\langle u , \rangle_L)$.
4. If $u \in W$, then $\langle u, 1 \rangle = \min(\langle u , \rangle_{L[W]}, u = \max(\langle - , u \rangle_{L[W]}), u = \sup_{L[W]}(\langle - , u \rangle_{L[W]} = \sup_{L[W]}(\langle - , u \rangle_L)$ and $\langle u, 1 \rangle = \inf_{L[W]}(\langle u , \rangle_{L[W]} = \inf_{L[W]}(\langle u , \rangle_{L[W]}$.

Proof. (1): Assume $(u, v)_L = \emptyset$ and $(u, v)_{L[W]} \neq \emptyset$. Then $(u, v)_{L[W]}$ is $\{\langle u, 1 \rangle\}$ with $u \in W \subseteq G^M(L)$. This contradicts $u = \inf_L(\langle u , \rangle_L)$.

(2): Let $u \in G(L)$. As in the proof of th lemma above, using $u = \sup_L(\langle - , u \rangle_L$, for every $v <_{L[W]} u$, one can take $v' \in L$ with $v <_{L[W]} v' <_{L[W]} u$. Then we are done.
(3): Similar to (2).
(4): The first and second are evident. Third follows from (2). The fourth is similar to (2). □

3. The simplest linearly ordered compactification

In this section, we fix a GO-space \( X = \langle X, <, \tau \rangle \). We will visualize the simplest linearly ordered compactification (denoted by \( lX \)) of \( X \).

First we remark:

**Lemma 3.1.** Let \( L \) be a linearly ordered compactification of a GO-space \( X \).

1. If \( u \in L \setminus X \), then \( u = \sup_L (\leftarrow, u)_L \) or \( u = \inf_L (u, \rightarrow)_L \).
2. If \( u \in L \) and \( u = \sup_L (\leftarrow, u)_L \), then \( u = \sup_L ((\leftarrow, u)_L \cap X) \).
3. If \( u \in L \) and \( u = \inf_L (u, \rightarrow)_L \), then \( u = \inf_L ((u, \rightarrow)_L \cap X) \).

To prove the lemma, use the density of \( X \).

Now we describe \( lX \). First let \( X_G \) denote the set of all gaps of the linearly ordered set \( \langle X, < \rangle \), that is,

\[ X_G = \{ \langle A, B \rangle : \langle A, B \rangle \text{ is a gap of } X \} \]

Remark that \( X_G \) does not depend on its GO-topology \( \tau \). We may assume \( X \setminus X_G = \emptyset \), in fact, this is a theorem of ZFC. Let \( X^* = \langle X^*, <_{X^*}, \lambda(<_{X^*}) \rangle \) be the LOTS described in section 1, that is,

\[ X^* = (X^- \times \{-1\}) \cup X \cup (X^+ \times \{1\}) \]

with the lexicographic order \( <_{X^*} \) under the identification \( X = X \times \{0\} \). Our \( lX \) is

\[ lX = X^* \cup X_G \]

with the order \( <_{lX} \), where for \( u, v \in lX \), \( u <_{lX} v \) is defined by

\[
\begin{cases}
  u, v \in X^* \text{ and } u <_{X^*} v, \\
  u = \langle A, B \rangle \in X_G, v = \langle x, i \rangle \in X^* \text{ and } x \in B, \\
  u = \langle x, i \rangle \in X^*, v = \langle A, B \rangle \in X_G \text{ and } x \in A, \\
  u = \langle A, B \rangle, v = \langle C, D \rangle \in X_G \text{ and } A \subset C,
\end{cases}
\]

where \( \langle x, 0 \rangle \) is identified with \( x \). Obviously \( <_{lX} \) extends \( <_{X^*} \), therefore it also extends \( <_X \). Also note that if \( X \) has no min (max), then \( \langle \emptyset, X \rangle \in X_G \) \( (\langle X, \emptyset \rangle \in X_G) \) and it is min \( lX \) (max \( lX \), respectively).

Define \( f : X^* \cup (X^*)_G \to lX \), where \( (X^*)_G \) is the set of all gaps in \( X^* \), by

\[
f(u) = \begin{cases}
  u & \text{if } u \in X^* \\
  \langle H \cap X, K \cap X \rangle & \text{if } u = \langle H, K \rangle \in (X^*)_G.
\end{cases}
\]
By the density of $X$ in $X^*$, $f$ is well-defined and an order isomorphism with $f \upharpoonright X = 1_X$. Since $X^* \cup (X^*)_G$ is a linearly ordered compactification of $X^*$, $lX$ is also a linearly ordered compactification of $X$. We show:

**Lemma 3.2.** Let $X$ be a GO-space. Then $lX$ is a linearly ordered compactification of $X$ such that $(u,v)_{lX} \neq \emptyset$ for every $u,v \in lX \setminus X$ with $u <_{lX} v$.

**Proof.** Let $u,v \in lX \setminus X$ with $u <_{lX} v$. The case $u,v \in X^* \setminus X$ follows from Lemma 1.4 (5), so we may assume $u \in lX \setminus X^* = X_G$, say $u = (A,B)$. Let assume $v \in X^*$, say $v = (x,i)$. It follows from $u <_{lX} v$ that $x \in B$. Since $B$ has no min, take $x' \in B$ with $x' <_X x$. Then $u <_{lX} x' <_{lX} v$. Next assume $v \in lX \setminus X^*$, say $v = (C,D)$. Then $A \subsetneq C$, so taking $x' \in C \setminus A$, we have $u <_{lX} x' <_{lX} v$. □

4. The structure of linearly ordered compactifications

We fix a linearly ordered set $\langle X, <_X \rangle$. In this section, from the need to distinguish between the topologies $\tau$'s on $\langle X, <_X \rangle$, we use the terminology $X_{\tau}$ for expressing the GO-space $\langle X, <_X, \tau \rangle$.

**Definition 4.1.** $L_X$ denotes the class of all linearly ordered compactifications of GO-spaces whose underlying linearly ordered set is $\langle X, <_X \rangle$. Also for a GO-space $X_{\tau} = (X, <_X, \tau)$, $L_{X_{\tau}}$ denotes the class of all linearly ordered compactifications of $X_{\tau}$. Note $L_X = \bigcup_{\tau \in GT_X} L_{X_{\tau}}$, where $GT_X$ is the set of all GO-topologies on $\langle X, <_X \rangle$, see section 1.

For $L_0, L_1 \in L_X$, define $L_0 \leq L_1$ if there is a continuous map $f : L_1 \to L_0$ such that $f \upharpoonright X = 1_X$. Obviously, the order $\leq$ is reflexive and transitive.

First we check:

**Lemma 4.2.** Let $L_0, L_1 \in L_X$ and assume that there is a map $f : L_1 \to L_0$ such that $f \upharpoonright X = 1_X$. Then the following are equivalent:

1. $f$ is continuous,
2. $f$ is 3-1, order preserving and onto.

**Proof.** $(2) \Rightarrow (1)$ follows from Lemma 2.1(1).

$(1) \Rightarrow (2)$: Assume that $f$ is continuous. Since $X = f[X] \subseteq f[L_1]$ and $X$ is dense in $L_0$, we have $f[L_1] = L_0$.

**Claim 1.** $f$ is order preserving.

**Proof.** Assume $u <_{L_1} u'$ and $f(u') <_{L_0} f(u)$. We will derive a contradiction. Since $L_0$ is a $T_2$ GO-space, there are disjoint convex open sets $U, U'$ in $L_0$ with $f(u) \in U, f(u') \in U'$. Because of the continuity of
Assuming that \( f \), one can take convex open sets \( V, V' \) in \( L_1 \) with \( u \in V, u' \in V' \) and \( f[V] \subseteq U, f[V'] \subseteq U' \). Then obviously \( V \cap V' = \emptyset \). Since \( X \) is dense in \( L_1 \), one can take \( x \in V \cap X, x' \in V' \cap X \). Then by \( u <_{L_1} u' \) and the convexity of \( V, V' \), we have \( x <_X x' \). By \( f(u') <_{L_o} f(u) \), the convexity of \( U, U' \), \( f(x) \in U \) and \( f(x') \in U' \), we have \( x' = f(x') <_{L_o} f(x) = x \), a contradiction.

\[ \square \]

**Claim 2.** If \( u <_{L_1} u' \), \( f(u) = f(u') \) and \( (u, u')_{L_1} \neq \emptyset \), then \( (u, u')_{L_1} = \{x\} \) for some \( x \in X \).

\[ \text{Proof.} \] Assuming \( u <_{L_1} u' \), \( f(u) = f(u') \) and \( (u, u')_{L_1} \neq \emptyset \), take \( x \) in \( (u, u')_{L_1} \cap X \). If \( (u, x)_{L_1} \neq \emptyset \) were true, then by taking \( x' \in (u, x)_{L_1} \cap X \), we have \( f(u) \leq f(x') \leq f(x) \leq f(u') \), thus \( x = f(x) = f(x') = x' \), a contradiction. So we have \( (u, x)_{L_1} = \emptyset \), similarly \( (x, u)_{L_1} = \emptyset \).

\[ \square \]

**Claim 3.** \( f \) is 3-1.

\[ \text{Proof.} \] Assume \( u_0 <_{L_1} u_1 <_{L_1} u_2 <_{L_1} u_3 \) and \( f(u_0) = f(u_1) = f(u_2) = f(u_3) \). It follows from \( (u_0, u_2) \neq \emptyset \) and Claim 2 that \( (u_0, u_2) = \{u_1\} \) and \( u_1 \in X \). Similarly we have \( (u_1, u_3) = \{u_2\} \) and \( u_2 \in X \). Now we have \( f(u_1) = u_1 < u_2 = f(u_2) \), a contradiction.

\[ \square \]

**Lemma 4.3.** Let \( L_0, L_1 \in \mathbb{L}_X \), say for each \( i \in 2 \), \( L_i \) is a linearly ordered compactification of \( X_{\tau_i} = (X, <_X, \tau_i) \). Assume that there is a continuous map \( f : L_1 \rightarrow L_0 \) such that \( f \upharpoonright X = 1_X \). The following are equivalent:

1. \( f \) is 2-1,
2. \( X^+_{\tau_1} \cap X^-_{\tau_1} \subseteq X^+_{\tau_0} \cup X^-_{\tau_0} \).

\[ \text{Proof.} \ (1) \rightarrow (2): \] Assume that there is \( x \) in \((X^+_{\tau_1} \cap X^-_{\tau_1}) \setminus (X^+_{\tau_0} \cup X^-_{\tau_0}) \).

It suffices to see the following.

**Claim.** \( f(\langle x, 1 \rangle) = f(\langle x, -1 \rangle) = x \).

\[ \text{Proof.} \] It follows from \( x < \langle x, 1 \rangle \in X^+_{\tau_1} \times \{1\} \subset X^+_{\tau_1} \) that \( x = f(x) \leq f(\langle x, 1 \rangle) \). If \( x < f(\langle x, 1 \rangle) \) were true, then using the density of \( X \) in \( L_0 \) we see \( (x, f(\langle x, 1 \rangle))_{L_0} = \emptyset \), thus \( \langle -, x \rangle_X \in \tau_0 \). On the other hand, by \( x \in X^+_{\tau_1} \), \( \langle -, x \rangle_X \notin \lambda(<X) \) holds. Therefore we have \( x \in X^+_{\tau_0} \), a contradiction. So we have \( x = f(\langle x, 1 \rangle), x = f(\langle x, -1 \rangle) \) is similar.

\[ \square \]

\( (2) \rightarrow (1): \) Assuming that \( f \) is not 2-1, pick \( u_0, u_1, u_2 \in L_1 \) such that \( u_0 <_{L_1} u_1 <_{L_1} u_2 \) and \( f(u_0) = f(u_1) = f(u_2) \). As in Claim 2 in the previous lemma, we have \((u_0, u_2)_{L_1} = \{u_1\} \) and \( u_1 \in X \). By \( f \upharpoonright X = 1_X \), we also have \( u_0, u_2 \notin X \). \( \langle -, u_1 \rangle_X \in \tau_1 \) and \( \langle u_1, - \rangle_X \in \tau_1 \).
are obvious. By $u_2 \in (u_1, \to)_{L_1}$ and the density of $X$, we have $(u_1, \to)_X \neq \emptyset$. If $(\leftarrow, u_1)_X \in \lambda(<_X)$ were true, then there is $x \in X$ such that $u_1 <_X x$ and $(u_1, x)_X = \emptyset$. By $u_2 \notin X$ and $(u_1, u_2)_{L_1} = \emptyset$, we have $u_2 <_X x$, thus $(u_1, x)_L_1 \neq \emptyset$, a contradiction. Therefore $(\leftarrow, u_1)_X \notin \lambda(<_X)$ holds, similarly we have $[u_1, \to)_X \notin \lambda(<_X)$. Now we see $u_1 \in X^+_\tau \cap \tilde{X}^-$. If $u_1 \in X^+_\tau$ were true, then by $u_1 < \langle u_1, 1 \rangle \in X^+_\tau \times \{1\} \subset X^*_\tau$ and $(u_1, \langle u_1, 1 \rangle)_{L_0} = \emptyset$, we have $f(u_2) = u_1 \in (\leftarrow, (u_1, 1))_{L_0}$. By continuity of $f$, there is an open neighborhood $V$ of $u_2$ in $L_1$ such that $f[V] \subset (\leftarrow, (u_1, 1))_{L_0}$. We may assume $V \subset (u_1, \to)_{L_1}$. Pick $x \in V \cap X$, then $u_2 <_{L_1} x$ and $x = f(x) \leq_{L_0} u_1 <_X x$, a contradiction. Thus we have $u_1 \notin X^+_\tau$, similarly we have $u_1 \notin X^-_\tau$.

Applying the lemma above to $\tau = \tau_0 = \tau_1$, we see:

**Corollary 4.4.** Let $L_0, L_1 \in L_X$, for some $\tau \in GT_X$. If there is a continuous map $f : L_1 \to L_0$ such that $f \upharpoonright X = 1_X$, then $f$ is 2-1,

**Lemma 4.5.** Let $L_0, L_1 \in L_X$. Then the following are equivalent:

1. $L_0 \leq L_1$ and $L_1 \leq L_0$,
2. there is a 1-1 continuous map $f : L_1 \to L_0$ such that $f \upharpoonright X = 1_X$,
3. there is an order isomorphism $f : L_1 \to L_0$ such that $f \upharpoonright X = 1_X$.

**Proof.** (3) $\Rightarrow$ (1) follows from the fact that an order isomorphism between LOT'S's is a homeomorphism.

1. $(1) \Rightarrow (2)$: Let $f : L_1 \to L_0$ and $g : L_0 \to L_1$ be continuous maps with $f \upharpoonright X = 1_X$ and $g \upharpoonright X = 1_X$. Then the combination $g \circ f$ has to be $1_{L_1}$, therefore $f$ is 1-1.

2. $(2) \Rightarrow (3)$: Let $f : L_1 \to L_0$ be a 1-1 continuous map with $f \upharpoonright X = 1_X$. It follows from Lemma 4.2 that $f$ is 1-1, order preserving onto, which means $f$ is an order isomorphism.

Note that if $L_0, L_1 \in L_X$ with $L_0 \leq L_1$ and $L_1 \leq L_0$, then $L_0, L_1 \in L_X$, for some $\tau \in GT_X$. If one of the equivalents in the lemma above is satisfied, then we identify $L_0$ with $L_1$. Under this identification, we will investigate the structure of the partially ordered sets $(L_X, \leq)$ and $(L_{X_\tau}, \leq)$. Remember that $X_G$ is the set of all gaps of $X$ and $L_{X_\tau} = X^*_\tau \cup X_G$ (in section 3, apply for $X = X_\tau$), where $X_\tau = \langle X, <_X, \tau \rangle$. Now let $X^M_G$ denotes the set of all middle gaps of $X$, that is,

$$X^M_G = \{ \langle A, B \rangle : \langle A, B \rangle \text{ is a middle gap of } X \}.$$  

Then $|X_G \setminus X^M_G| \leq 2$ and note that $X_G$ and $X^M_G$ only depend on the linearly ordered set $\langle X, <_X \rangle$. Also remember the definitions of $G(L)$.
The inclusion Let If To see the inclusion $f$

Claim 1. $X^M_G \subseteq G^M(lX_\tau)$ and $X_G \subseteq G(lX_\tau)$ hold.

Proof. Let $u \in X^M_G$, say $u = \langle A, B \rangle$. Because of $A \neq \emptyset$ and $B \neq \emptyset$, we have $(\leftarrow, u)_{lX_\tau} \neq \emptyset$ and $(u, \rightarrow)_{lX_\tau} \neq \emptyset$. Assume $v = \sup_{lX_\tau}(\leftarrow, u)_{lX_\tau} <_{lX_\tau} u$. First assume $v \in X$. Since $v \in A$ and $A$ has no max, we can take $x \in A$ with $v <_X x <_{lX_\tau} u$, this contradicts the definition of $v$. Next assume $v \notin X$. It follows from Lemma 3.2 that $(v, u)_{lX_\tau} \neq \emptyset$, also contradicts the definition of $v$. Therefore we have $\sup_{lX_\tau}(\leftarrow, u)_{lX_\tau} = u$. Similarly we have $\inf_{lX_\tau}(u, \rightarrow)_{lX_\tau} = u$. Now $X_G \subseteq G(lX_\tau)$ is obvious.

Now for every $W \subseteq X^M_G$, using the notation in section 2, we let

$$l_W X_\tau = (lX_\tau)[W].$$

Then $lX_\tau = l_0 X_\tau$. We also let

$$LX_\tau = l^+_X X_\tau.$$

Later we will see that $lX_\tau$ is the minimal and $LX_\tau$ is the maximal in $\langle L_{X_\tau}, \leq \rangle$ and that $lX_{\lambda(\prec_X)}$ is the minimal and $LX_{\tau(X_\tau, X_\tau)}$ is the maximal in $\langle L_X, \leq \rangle$.

Lemma 4.7. If $\tau \in GT_X$, then $L_{X_\tau} = \{l_W X_\tau : W \subseteq X^M_G\}$.

Proof. The inclusion “$\supseteq$” follows from Lemma 4.6 and Corollary 2.4.

To see the inclusion “$\subseteq$”, let $L \in L_{X_\tau}$. Define $f : L \to lX_\tau$ by

$$f(u) = \begin{cases} \{\{x \in X : x <_L u\}, \{x \in X : u <_L x\}\} & \text{if } u \in L \setminus X^*_\tau, \\ u & \text{otherwise}. \end{cases}$$

The following claim shows that $f$ is well-defined and onto.

Claim 1. $f[L \setminus X^*_\tau] = X_G$.

Proof. To see the inclusion “$\subseteq$”, let $u \in L \setminus X^*_\tau$, $A = \{x \in X : x <_L u\}$ and $B = \{x \in X : u <_L x\}$. Assume that $A$ has the maximal element $x_0$, then by the density of $X$, $(x_0, u)_L = \emptyset$ holds. If $x_0 \in X^+_\tau$ were true, then we have $u = \langle x_0, 1 \rangle \in X^+_\tau \times \{1\} \subseteq X^*_\tau$, see Lemma 1.4(1), a contradiction. Thus we have $x_0 \notin X^+_\tau$. Because of $(\leftarrow, x_0)_X = A \in \tau$, we have $(\leftarrow, x_0)_X \in X(\prec_X)$. Since $(x_0, \rightarrow)_L \neq \emptyset$ holds (u witnesses this), we have $(x_0, \rightarrow)_X \neq \emptyset$. Thus there is $z \in X$ with $z >_X x$ and $(x_0, z)_X = \emptyset$. It follows from $(x_0, u)_L = \emptyset$, $u \notin X$ and $z \notin X$ that $u <_L z$ therefore $(x_0, z)_L \neq \emptyset$ and hence $(x_0, z)_X \neq \emptyset$, a contradiction. We have shown that $A$ has no max, similarly $B$ has no min. This means $f(u) \in X_G$. 

To see the inclusion “⊇”, let \( w \in X_G \), say \( w = \langle A, B \rangle \). Putting \( u = \sup_L A \), we see \( f(u) = w \).

**Claim 2.** \( f \) is order preserving.

**Proof.** Let \( u, v \in L \) with \( u <_L v \). We will see \( f(u) \leq_{L_X} f(v) \). By \( X_r^* \subseteq L \), we may assume \( u \notin X_r^* \) or \( v \notin X_r^* \). But in the case \( u \notin X_r^* \) and \( v \notin X_r^* \), it is obvious by the definition of \( f \) and the claim above. We consider the case \( u \notin X_r^* \) and \( v \in X_r^* \). When \( v \in X \), by \( v \in \{ x \in X : u <_L x \} \), we see \( f(u) <_{L_X} v = f(v) \). When \( v = \langle x, 1 \rangle \) for some \( x \in X_r^+ \), we have \( u <_L x \), see Lemma 1.4(1). Now we have \( f(u) <_{L_X} x <_{L_X} v = f(v) \). When \( v = \langle x, -1 \rangle \) for some \( x \in X_r^- \), by Lemma 1.4(2) and (3), we can take \( z \in (u, v)_L \cap X \). Then \( f(u) <_{L_X} z <_{L_X} v = f(v) \). The case \( u \in X_r^+ \) and \( v \notin X_r^* \) is similar. \( \square \)

**Claim 3.** \( f \) is 2-1.

**Proof.** Because of \( f \upharpoonright X_r^* = 1_X \), \( f(\varnothing) = X_G \) and \( X_r^* \cap X_G = \emptyset \), it suffices to see that \( f \upharpoonright (L \setminus X_r^*) \) is 2-1. So assume that for some \( u_0, u_1, u_2 \in L \setminus X_r^* \), \( u_0 < u_1 < u_2 \), \( f(u_0) = f(u_1) = f(u_2) \) holds.

Applying the density of \( X \) to \( (u_0, u_2)_L \), we can take \( x \in (u_0, u_2)_L \cap X \). Then by \( u_0 < x < u_2 \), we have \( f(u_0) < x < f(u_1) \), a contradiction. \( \square \)

Now let \( W = \{ w \in X_G : |f^{-1}(\{ w \})| = 2 \} \). We have:

**Claim 4.** \( W \subseteq X_G^M \).

**Proof.** Let \( w \in W \) and we fix \( u_0, u_1 \in L \setminus X_r^* \) with \( u_0 < u_1 \) and \( w = f(u_0) = f(u_1) \). If \( (u_0, u_1)_L \neq \emptyset \) were true, then by taking \( x \in (u_0, u_1)_L \cap X \), we have \( f(u_0) < x < f(u_1) \) as above, a contradiction. Thus we have \( (u_0, u_1)_L = \emptyset \). By \( (\leftarrow, u_1)_L \neq \emptyset \), take \( x \in (\leftarrow, u_1)_L \cap X \). Then we have \( x < u_0 \) for some \( x \in X \). Moreover by \( (u_0, \rightarrow)_L \neq \emptyset \), we have \( u_0 < y \) for some \( y \in X \). This means \( w = f(u_0) \in X_G^M \). \( \square \)

Now by Lemma 2.1 (2), \( \tilde{f} : L \to (lX_r)_W \) is an order isomorphism with \( \tilde{f} \upharpoonright X = 1_X \). By Lemma 4.5, we have \( L = lW X_r \).

**Lemma 4.8.** If for each \( i \in \mathbb{I} \), \( X_{\tau_i} = \langle X, <_X, \tau_i \rangle \) be a GO-space and \( W_i \subseteq X_G^M \). Then the following are equivalent:

1. \( lW_1 X_{\tau_1} \geq lW_0 X_{\tau_0} \).
2. \( \tau_1 \geq \tau_0 \) and \( W_1 \supseteq W_0 \).

**Proof.** Note that \( \tau_1 \supseteq \tau_0 \) is equivalent to the both \( X_{\tau_1}^+ \supseteq X_{\tau_0}^+ \) and \( X_{\tau_1}^- \supseteq X_{\tau_0}^- \), see Proposition 1.3.
THE STRUCTURE OF THE LINEARLY ORDERED COMPACTIFICATIONS

(2) → (1): Let \( \tau_1 \supseteq \tau_0 \) and \( W_1 \supseteq W_0 \) and define \( f : l_{W_1}X_{\tau_1} \to l_{W_0}X_{\tau_0} \) by

\[
\begin{aligned}
f(u) = & \begin{cases} 
  x & \text{if } u = (x, 1) \text{ for some } x \in X_{\tau_1}^+ \setminus X_{\tau_0}^+, \\
  x & \text{if } u = (x, -1) \text{ for some } x \in X_{\tau_1}^- \setminus X_{\tau_0}^-, \\
  c & \text{if } u = (c, 1) \text{ for some } c \in W_1 \setminus W_0, \\
  u & \text{otherwise}. 
\end{cases}
\end{aligned}
\]

Obviously \( f \) is 3-1, order preserving and onto with \( f \restriction X = 1_X \). By Lemma 4.2, we have \( l_{W_1}X_{\tau_1} \geq l_{W_0}X_{\tau_0} \).

(1) → (2): Let \( l : l_{W_1}X_{\tau_1} \to l_{W_0}X_{\tau_0} \) be a continuous map with \( f \restriction X = 1_X \). Since \( 1_X \) is a continuous map from \( X_{\tau_1} \) to \( X_{\tau_0} \), we have \( \tau_1 \supseteq \tau_0 \). It suffices to see \( W_1 \supseteq W_0 \). So let \( c \in W_0 \) and say \( c = (A, B) \), where \( (A, B) \) is a gap of \( X \) with \( A \neq \emptyset \) and \( B \neq \emptyset \). Since \( f \) is onto and \( (c, 1) \in W_0 \times \{1\} \subseteq l_{W_0}X_{\tau_0} \), there is \( u \in l_{W_1}X_{\tau_1} \) with \( f(u) = (c, 1) \). It follows from \( (c, 1) \not\in X \) that \( u \not\in X \).

**Claim 1.** \( u \not\in X_{\tau_1}^* \).

**Proof.** Assume \( u \in X_{\tau_1}^* \). By \( u \not\in X \), we have \( u \in X_{\tau_1}^* \times \{1\} \cup X_{\tau_1}^- \times \{-1\} \).

First we consider the case “\( u \in X_{\tau_1}^* \times \{1\} \)”, say \( u = (x, 1) \) for some \( x \in X_{\tau_1}^+ \). When \( x \in A \), take \( z \in A \) with \( x <_X z \). Then by \( u <_{l_{W_1}X_{\tau_1}} z \) (see Lemma 1.4(1)), we have \( f(u) \leq f(z) = z < c < (c, 1) = f(u) \), a contradiction. When \( x \in B \), take \( z \in B \) with \( z <_X x \). Then by \( z <_{l_{W_1}X_{\tau_1}} u \), we have \( f(u) = (c, 1) < z = f(z) \leq f(u) \), a contradiction.

Next we consider the case “\( u \in X_{\tau_1}^- \times \{-1\} \)”, say \( u = (x, -1) \) for some \( x \in X_{\tau_1}^- \). When \( x \in A \), by \( u < x \), we have \( f(u) \leq f(x) = x < c < (c, 1) = f(u) \), a contradiction. When \( x \in B \), take \( z \in B \) with \( z <_X x \). Then by \( z <_{l_{W_1}X_{\tau_1}} u \), we have \( z = f(z) \leq f(u) = (c, 1) < z \), a contradiction.

\( \square \)

**Claim 2.** \( u \not\in X_G \).

**Proof.** Assume \( u \in X_G \), say \( u = (C, D) \). If \( c < u \) were true, then by taking \( x \in C \setminus A \), we have \( c < x < u \). Therefore we have \( f(u) = (c, 1) < x = f(x) \leq f(u) \), a contradiction. If \( u < c \) were true, then by taking \( x \in A \setminus C \), we have \( u < x < c \). Therefore we have \( (c, 1) = f(u) \leq f(x) = x < c < (c, 1) \), a contradiction. Thus \( u = c \) holds. Since \( f \) is order preserving, continuous and \( f(c) = (c, 1) \), there is \( v \in l_{W_1}X_{\tau_1} \) such that \( v <_{l_{W_1}X_{\tau_1}} c \) and \( f((v, -)l_{W_1}X_{\tau_1}) \subseteq (c, -)l_{W_0}X_{\tau_0} \). Since \( c \) is a gap and \( v < c \), we have \( (v, c)l_{W_1}X_{\tau_1} \not\subseteq \emptyset \). Take \( x \in (v, c)l_{W_1}X_{\tau_1} \cap X \), then we have \( f(x) = (c, 1) \), a contradiction.

\( \square \)
By Claims above and \( l_{W_1}X_{\tau_1} = (X_{\tau_1}^s \cup X_G) \cup W_1 \times \{1\} \), we see \( u \in W_1 \times \{1\} \), say \( u = \langle c', 1 \rangle \) with \( c' = \langle A', B' \rangle \) for some \( c' \in W_1 \). The following Claim completes the proof.

**Claim 3.** \( c = c' \).

**Proof.** If \( A \not\subseteq A' \) were true, then by taking \( x \in A' \setminus A \), we have \( c < x < c' < \langle c', 1 \rangle = u \) in \( l_{W_1}X_{\tau_1} \). Now we have \( f(u) = \langle c, 1 \rangle < x = f(x) \leq f(u) \), a contradiction. If \( A' \not\subseteq A \) were true, then by taking \( x \in A \setminus A' \), we have \( c' < x < c \). By \( u = \langle c', 1 \rangle < x \), we have \( f(u) \leq f(x) = x < c < \langle c, 1 \rangle = f(u) \), a contradiction. Thus we see \( u = u' \).

\[ \square \]

Now we have:

**Theorem 4.9.** Let \( \langle X, <_X \rangle \) be a linearly ordered set. Then the following hold:

1. The partial ordered set \( \langle L_X, \leq \rangle \) is order isomorphic to

   \[ \langle \mathcal{P}(X_R), \subseteq \rangle \times \langle \mathcal{P}(X_L), \subseteq \rangle \times \langle \mathcal{P}(X^M_G), \subseteq \rangle, \]

   therefore \( lX_\lambda(<_X) \) is the minimal and \( LX_\tau(X_R, X_L) \) is the maximal in \( \langle L_X, \leq \rangle \).

2. For each \( \tau \in GT_X \), the partial ordered set \( \langle L_{X_\tau}, \leq \rangle \) is order isomorphic to

   \[ \langle \mathcal{P}(X^M_G), \subseteq \rangle, \]

   therefore \( lX_\tau \) is the minimal and \( LX_\tau \) is the maximal in \( \langle L_{X_\tau}, \leq \rangle \).

From (2), we see that the structure of \( \langle L_{X_\tau}, \leq \rangle \) does not depend on its topology \( \tau \).

**Example 4.10.** Let \( X = \mathbb{R} \) be the LOTS, then \( X_R = X_L = \mathbb{R} \) and \( X^M_G = \emptyset \). Therefore \( \langle L_\mathbb{R}, \leq \rangle \) is order isomorphic to \( \langle \mathcal{P}(\mathbb{R}), \subseteq \rangle \times \langle \mathcal{P}(\mathbb{R}), \subseteq \rangle \). Since \( X^M_G = \emptyset \), each of \( \mathbb{R}, S \) and \( M \) has the unique linearly ordered compactification \( \mathbb{R} \cup \{-\infty, \infty\}, (\mathbb{R} \cup \{-\infty, \infty\}) \cup \mathbb{R} \times \{1\} \) and \( \mathbb{R} \cup \{-\infty, \infty\} \cup \mathbb{R} \times \{1\} \) respectively, where \(-\infty = \langle 0, \mathbb{R} \rangle, \infty = \langle \mathbb{R}, 0 \rangle \) are the end gaps. The minimal in \( \langle L_\mathbb{R}, \leq \rangle \) is \( \mathbb{R} \cup \{-\infty, \infty\} \) and the maximal in \( \langle L_\mathbb{R}, \leq \rangle \) is \( \mathbb{R} \times \{-1, 0, 1\} \cup \{-\infty, \infty\} \), where \( \mathbb{R} \) is identified with \( \mathbb{R} \times \{0\} \).

**Example 4.11.** Let \( X = \mathbb{Q} \) be the LOTS. Then \( X_R = X_L = \mathbb{Q} \). For every middle gap \( \langle A, B \rangle \) of \( \mathbb{Q} \), assign \( \sup_B A \in \mathbb{P} \). Using this assignment, we may consider \( X_G = \mathbb{P} \cup \{-\infty, \infty\} \) and \( X^M_G = \mathbb{P} \), where \(-\infty, \infty \) are the end gaps of \( \mathbb{Q} \). Therefore \( \langle L_\mathbb{Q}, \leq \rangle \) is order isomorphic to \( \langle \mathcal{P}(\mathbb{Q}), \subseteq \rangle \times \langle \mathcal{P}(\mathbb{Q}), \subseteq \rangle \times \langle \mathcal{P}(\mathbb{P}), \subseteq \rangle \). \( lQ = l_0\mathbb{Q} = \mathbb{Q} \cup \mathbb{P} \cup \{-\infty, \infty\} \),
which is identified with $\mathbb{R} \cup \{-\infty, \infty\}$, is the minimal in $\langle \mathbb{L}_Q, \leq \rangle$. $l_PQ_{\tau(\mathbb{Q}, P)} = (\mathbb{R} \cup \{-\infty, \infty\} \cup \mathbb{Q} \times \{-1, 1\}) \cup \mathbb{P} \times \{1\}$ is the maximal in $\langle \mathbb{L}_Q, \leq \rangle$.

Similarly we see that $\langle \mathbb{L}_P, \leq \rangle$ is order isomorphic to $\langle \mathcal{P}(\mathbb{P}), \subseteq \rangle \times \langle \mathcal{P}(\mathbb{P}), \subseteq \rangle \times \langle \mathcal{P}(\mathbb{Q}), \subseteq \rangle$.

**Example 4.12.** Let $X_\tau$ be the GO-space $(0, 1) \cup (1, 2) \cup [3, 4] \cup (5, 6]$ with the usual order and the subspace topology $\tau$ in $\mathbb{R}$. It has one end gap $0 = \langle 0, X \rangle$. There are two middle gaps $c_0 = \langle (0, 1), (1, 2) \cup [3, 4] \cup (5, 6) \rangle$ and $c_1 = \langle (0, 1) \cup (1, 2) \cup [3, 4], (5, 6) \rangle$. Thus $X^+_\tau = \emptyset$ and $X^- = [3], X_G = \{0, c_0, c_1\}$ and $X^+_G = \{c_0, c_1\}$. So there are $2^2 = 4$ linearly ordered compactifications of $X_\tau$. With appropriate identifications,

$$IX_\tau = [0, 1) \cup (1, 2) \cup [3, 4] \cup (5, 6] \cup \{3, -1\} \cup \{c_0, c_1\}.$$ 

Identifying $2 = \langle 3, -1 \rangle$,

$$IX_\tau = [0, 1) \cup \{c_0\} \cup (1, 2) \cup [3, 4] \cup \{c_1\} \cup (5, 6],$$

$$l_{\{c_0\}} X_\tau = [0, 1) \cup \{c_0, \langle c_0, 1 \rangle\} \cup (1, 2) \cup [3, 4] \cup \{c_1\} \cup (5, 6],$$

$$l_{\{c_1\}} X_\tau = [0, 1) \cup \{c_0\} \cup (1, 2) \cup [3, 4] \cup \{c_1, \langle c_1, 1 \rangle\} \cup (5, 6],$$

$$LX_\tau = [0, 1) \cup \{c_0, \langle c_0, 1 \rangle\} \cup (1, 2) \cup [3, 4] \cup \{c_1, \langle c_1, 1 \rangle\} \cup (5, 6].$$

Moreover by identifying $c_0 = 1$, $[0, 1) \cup \{c_0\} \cup (1, 2)$ can be identified with $[0, 2]$. Also identifying $c_1 = 4$ and $(5, 6] = (4, 5], [3, 4] \cup \{c_1\} \cup (5, 6]$ can be identified with $[3, 5]$. Thus topologically $lX_\tau$ can be considered as $[0, 2] \cup [3, 5]$. Similarly we can identify as $l_{\{c_0\}} X_\tau = [0, 2] \cup [3, 5] \cup \{1, 1\}, l_{\{c_1\}} X_\tau = [0, 2] \cup [3, 5] \cup \{4, 1\}$ and $l_{\{c_0, c_1\}} X_\tau = [0, 2] \cup [3, 5] \cup \{1, 1, \langle 4, 1 \rangle\}$. Note that $l_{\{c_0\}} X_\tau$ and $l_{\{c_1\}} X_\tau$ are homeomorphic, but they are different as linearly ordered compactifications.

**Example 4.13.** Let $X = (0, 1) \cup (1, 2) \cup [3, 4] \cup (5, 6]$ and $<_X$ be the restriction of the usual order on $\mathbb{R}$, that is, the underlying linearly ordered set of the previous example, so $X^+_G = \{c_0, c_1\}$. Then $\langle \mathbb{L}_X, \leq \rangle$ is order isomorphic to $\langle \mathcal{P}((0, 1) \cup (1, 2) \cup [3, 4] \cup (5, 6]), \subseteq \rangle \times \langle \mathcal{P}((0, 1) \cup (1, 2) \cup [3, 4] \cup (5, 6)), \subseteq \rangle \times \langle \mathcal{P}(\{c_0, c_1\}), \subseteq \rangle$. The minimal in $\langle \mathbb{L}_X, \leq \rangle$ is $\langle \{0, 0\} \cup (0, 1) \cup \{1, 1\}, \{c_0\} \cup (1, 2) \cup \{c_1\} \cup (5, 6],$ and the maximal in $\langle \mathbb{L}_X, \leq \rangle$ is $\langle \{0, 0\} \cup (0, 1) \cup \{1, 1\}, \{c_0\} \cup (1, 2) \cup \{c_1\} \cup (5, 6] \cup \{1, 1, \langle 4, 1 \rangle\}\rangle$.

**Example 4.14.** Let $X_\tau$ be a subspace of an ordinal $\alpha$ with the usual order and the subspace topology $\tau$. Taking a large enough ordinal, we may assume $\alpha$ is a successor ordinal, so it is compact. Since the order is a well-order, there are no middle gaps of $X_\tau$, but $\infty$ can exist. So $X^+_G = \emptyset$, thus $X_\tau$ has the unique linearly ordered compactification. The closure $\text{Cl}_\alpha X_\tau$ of $X_\tau$ in $\alpha$ is such a unique one.
Example 4.15. Let $X = \beta$ be an ordinal. Since $X_L = \text{Lim}(\beta)$, $X_R = X^M = \emptyset$, $\langle L_\beta, \leq \rangle$ is order isomorphic to $\langle P(\text{Lim}(\beta)), \subseteq \rangle$. where $\text{Lim}(\beta)$ denotes the all limit ordinals in $\beta$. Note that if $X_\tau$ is that in the previous example, then by enumerating $X_\tau = \{x(\gamma) : \gamma < \beta\}$ with the increasing order for some $\beta$, we may consider that the underlying linearly ordered set of $X_\tau$ is $\beta$.
